

3.1 → RAR Classification

- 3.1.1 → Importance of credit rating
- Goal is to separate risk to classes the more risk to each group the more homogeneous, thus resulting in more Stability.
 - credit rating means when you change the same risk subject of homogeneity
 - A = rating, and under each rating there is a score that represents more or more relative ratings
 - Impairment
 - risk changes
 - 1) dependent on a more refined manner,
 - 2) become distribution, or
 - 3) dependent on various risk-rating classes only
 - especially in this is Assessable Solution.
 - "Ranking the credit" is using risk characteristics + technical criteria, to select the lower-risk ratings (homogeneity)
- 3.1.2 → Criteria for evaluating rating methods
- The first stage in classification methodology is to identify the rating variables that will be used to classify risks. The criteria for evaluating the appropriateness of rating variables can be grouped into four categories:
- 1) Statistical Criteria
 - a) homogeneity → different levels of the rating variable should have different expected rates that are statistically significant & stable over time
 - b) homogeneity → the risks within the same level should have similar expected rates
 - c) Creditability → Each level should be large enough to allow reliable estimates of rates
 - 2) Practical Criteria
 - a) Objectivity → clear & measurable
 - b) Transparency → administrator → clear to which standards associated parameters benefit
 - c) Verifiability → not easily manipulated & easily verifiable
 - 3) Legal Criteria
 - a) Adaptability → system should be adaptable for all risks from high-risk to low-risk but ensure
 - b) Causality → A clear cause-and-effect between a rating variable & expected losses with respect to credit acceptability of the classification
 - c) Controllability → rating method generally prior to have some degree of control over the class to which they belong & the ability to determine the premium charged (is a loan amount, whether or not a security system is installed)
 - d) Policy Goals → not defined in policy are ignored
 - 4) Best criteria → follows appropriate laws
 - Classification methods → groups risks on similar characteristics / loss frequency } → Both use historical data & risk characteristics to determine a rate
 - appropriate when ratings a homogeneous group of risks
 - Individual risk ratings → tailored to the individual interest
 - Standard rates set by the law use relative rating plan
- Work of Qualifier → "EVALUATE" means DECLASSIFIED & RECLASSIFIED (very long)

3.1.3 → Univariate classification

- Goal → determine relationships for each level of a rating variable → (c) determinants for differentials by analyzing historical experience of each level of a rating variable independently
- There are three approaches
- Pure premium approach
- The basic pure premium approach determines the business relationships by comparing the expected pure premium for each risk class with a rating variable.
 - when using the pure premium approach, the need to avoid a double count the loss & ALAE depends on the nature of the portfolio.
 - Data should be adjusted for comparability & categorical events prior to a classification analysis.
 - The table below shows the indicated relativity for each territory using the pure premium approach
- | | (1) | (2) | (3) | (4) | (5) | (6) |
|-------|-----------|-------------|-------------|------------------------|------------------------------|---------|
| | Territory | Exposures | Loss & ALAE | Indicated Pure Premium | Indicated Relativity to Base | (5)/(4) |
| 1 | 300 | \$15,698.08 | \$52.33 | 0.7696 | 0.7231 | 0.94 |
| 2 | 390 | \$28,221.07 | \$72.36 | 1.0643 | 1.0000 | 1.00 |
| 3 | 310 | \$24,072.96 | \$77.65 | 1.1421 | 1.0731 | 1.07 |
| Total | 1,000 | \$67,992.11 | \$201.34 | 1.0000 | 0.9396 | |
- Best rating approach
- The best rating approach determines the indicated relativity by comparing the LRI for each risk class with a rating variable. When using this approach, EP should be limited to the current level for each class in risk.
 - The table below shows the indicated relativity for each territory using the LR approach.
- | | (1) | (2) | (3) | (4) | (5) | (6) |
|-------|-----------|-------------|-------------|-----------------|------------------------------|---------|
| | Territory | Exposures | Loss & ALAE | Adjusted Factor | Indicated Relativity to Base | (5)/(4) |
| 1 | 300 | \$15,698.08 | \$52.33 | 0.6000 | 0.6000 | 0.6000 |
| 2 | 390 | \$28,221.07 | \$72.36 | 1.0000 | 1.0000 | 1.0000 |
| 3 | 310 | \$24,072.96 | \$77.65 | 1.2000 | 1.2000 | 1.2000 |
| Total | 1,000 | \$67,992.11 | \$201.34 | 1.0000 | 1.0000 | 1.0000 |
- Adjusted pure premium approach
- The LR approach requires premium at each risk level of the rating variable, which may not always be available or practical to obtain. In such cases, it is necessary to use the pure premium approach. To minimize the impact of any distribution bias, the pure premium approach can be performed using exposures adjusted to the exposure-weighted average relativity of all other variables.
 - The exposure-weighted AOS relativity for each territory is calculated as follows:
- | | AOI | Charged AOI Factor | Exposures by Territory | | |
|--|------|--------------------|------------------------|--------|--------|
| | | | 1 | 2 | 3 |
| Low | 0.80 | 10 | 130 | 150 | |
| Medium | 1.00 | 110 | 120 | 120 | |
| High | 1.36 | 180 | 140 | 40 | |
| Weighted Avg AOI Relativity by Territory | | | 1.2093 | 1.0626 | 0.9497 |
- For example, the weighted average AOI relativity of territory 1 is
- $$\frac{(0.8 \times 10) + (1.0 \times 110) + (1.36 \times 180)}{(10 + 110 + 180)} = 1.2093$$
- The table below shows the indicated relativity for each territory using the RP approach w/ adjusted exposures
- | | (1) | (2) | (3) | (4) | (5) | (6) |
|-------|-----------|-------------|-------------|-----------------|------------------------------|---------|
| | Territory | Exposures | Loss & ALAE | Adjusted Factor | Indicated Relativity to Base | (5)/(4) |
| 1 | 300 | \$15,698.08 | \$52.33 | 0.6000 | 0.6000 | 0.6000 |
| 2 | 390 | \$28,221.07 | \$72.36 | 1.0000 | 1.0000 | 1.0000 |
| 3 | 310 | \$24,072.96 | \$77.65 | 1.2000 | 1.2000 | 1.2000 |
| Total | 1,000 | \$67,992.11 | \$201.34 | 1.0000 | 1.0000 | 1.0000 |
- As the exposures have been adjusted using the current amount of exposure, the indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach. The indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach.
- Adjusted pure premium approach
- The LR approach requires premium at each risk level of the rating variable, which may not always be available or practical to obtain. In such cases, it is necessary to use the pure premium approach. To minimize the impact of any distribution bias, the pure premium approach can be performed using exposures adjusted to the exposure-weighted average relativity of all other variables.
 - The exposure-weighted AOS relativity for each territory is calculated as follows:
- | | AOI | Charged AOI Factor | Exposures by Territory | | |
|--|------|--------------------|------------------------|--------|--------|
| | | | 1 | 2 | 3 |
| Low | 0.80 | 10 | 130 | 150 | |
| Medium | 1.00 | 110 | 120 | 120 | |
| High | 1.36 | 180 | 140 | 40 | |
| Weighted Avg AOI Relativity by Territory | | | 1.2093 | 1.0626 | 0.9497 |
- For example, the weighted average AOI relativity of territory 1 is
- $$\frac{(0.8 \times 10) + (1.0 \times 110) + (1.36 \times 180)}{(10 + 110 + 180)} = 1.2093$$
- The table below shows the indicated relativity for each territory using the RP approach w/ adjusted exposures
- | | (1) | (2) | (3) | (4) | (5) | (6) |
|-------|-----------|-------------|-------------|-----------------|------------------------------|---------|
| | Territory | Exposures | Loss & ALAE | Adjusted Factor | Indicated Relativity to Base | (5)/(4) |
| 1 | 300 | \$15,698.08 | \$52.33 | 0.6000 | 0.6000 | 0.6000 |
| 2 | 390 | \$28,221.07 | \$72.36 | 1.0000 | 1.0000 | 1.0000 |
| 3 | 310 | \$24,072.96 | \$77.65 | 1.2000 | 1.2000 | 1.2000 |
| Total | 1,000 | \$67,992.11 | \$201.34 | 1.0000 | 1.0000 | 1.0000 |
- As the exposures have been adjusted using the current amount of exposure, the indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach. The indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach.
- Adjusted pure premium approach

| Medium | 1.00 | 110 | 120 | 120 | |
| High | 1.36 | 180 | 140 | 40 | |
| Weighted Avg AOI Relativity by Territory | | | 1.2093 | 1.0626 | 0.9497 |
- For example, the weighted average AOI relativity of territory 1 is
- $$\frac{(0.8 \times 10) + (1.0 \times 110) + (1.36 \times 180)}{(10 + 110 + 180)} = 1.2093$$
- The table below shows the indicated relativity for each territory using the RP approach w/ adjusted exposures
- | | (1) | (2) | (3) | (4) | (5) | (6) |
|-------|-----------|-------------|-------------|-----------------|------------------------------|---------|
| | Territory | Exposures | Loss & ALAE | Adjusted Factor | Indicated Relativity to Base | (5)/(4) |
| 1 | 300 | \$15,698.08 | \$52.33 | 0.6000 | 0.6000 | 0.6000 |
| 2 | 390 | \$28,221.07 | \$72.36 | 1.0000 | 1.0000 | 1.0000 |
| 3 | 310 | \$24,072.96 | \$77.65 | 1.2000 | 1.2000 | 1.2000 |
| Total | 1,000 | \$67,992.11 | \$201.34 | 1.0000 | 1.0000 | 1.0000 |
- As the exposures have been adjusted using the current amount of exposure, the indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach. The indicated relativity for each risk class is the same as the indicated relativity for each risk class in the pure premium approach.
- Adjusted pure premium approach
- The LR approach requires premium at each risk level of the rating variable, which may not always be available or practical to obtain. In such cases, it is necessary to use the pure premium approach. To minimize the impact of any distribution bias, the pure premium approach can be performed using exposures adjusted to the exposure-weighted average relativity of all other variables.
 - The exposure-weighted AOS
